Retigabine is a novel anticonvulsant and a pharmacological modulator of neuronal M-currents that has been demonstrated to be effective in various animal models of epilepsy. In the present study, the in vivo anticonvulsant activity of retigabine was validated and the therapeutic potential of retigabine in a rat model of kainic acid-

induced neuronal death was assessed. The seizure threshold to electroshock was not altered in rats treated with retigabine, and oral dosing of retigabine was not effective in preventing tonic-clonic seizures induced by repetitive systemic administration of kainic acid. In contrast, however, oral administration of retigabine 30 min before a single systemic injection of kainic acid significantly reduced the duration of the initial stage of the seizures. In the hippocampal slice preparation, retigabine (10 and 30 microM) increased the amplitude of m-current and effectively enhanced the neuroprotective action of agents that inhibit m-current, including valproate, N-acetyl-l-aspartyl-l-glutamate (NAAG), N-acetylaspartate (NAA), and magnesium. In the neuroprotection experiments, the extent of neuronal death induced by N-methyl-D-aspartate (NMDA) was reduced by retigabine, but retigabine alone was ineffective. The results demonstrate that retigabine possesses in vivo anticonvulsant activity and that retigabine enhances neuroprotection in a model of neuronal death.Lithium-Ion Battery Could Soon Get a Boost with Nanomaterial Published on February 20, 2013.
